# Package **Pyliferisk**

# November 2, 2019

**Type**: Python Package

Version: 1.11

Author: Francisco Gárate

Contact: fgaratesantiago@gmail.com

License: GPLv3

Repository: https://github.com/franciscogarate/pyliferisk

Abstract: A python library for life actuarial calculations. Simple, powerful and easy-to-use.

This document aims to be the only necessary and authoritative source of information about pyliferisk, usable as a comprehensive reference, an user guide, and tutorial all-in-one. It also includes a sample of illustrative and common examples of actuarial calculations.

Pyliferisk is compatible with both version Python 3.x and 2.7 and has no dependencies other than the Python Standard Library, making it amazingly fast.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details. The author does not take any legal responsibility for the accuracy, completeness, or usefulness of the information herein.

## 1 Introduction

Pyliferisk is an open library written in Python for life and actuarial calculation contracts, based on commonly used methodologies among actuaries (International Actuarial Notation).

This library is able to cover all life contingencies risks (since the actuarial formulas follow the International Actuarial Notation), as well as to support the main insurance products: Term Life, Whole Life, Annuities and Universal Life. Additionally, the library can be easily tailored to any particular or local specifications, since Python is a very intuitive language.

It is ideal not only for academic purposes but also for professional use by actuaries (implementation of premiums and reserves modules) or by auditors (validation of reserves or capital risk models such as parallel runs).

This library is distributed as a single file module and has no dependencies other than the Python Standard Library, making it amazingly fast. Additionally, the package includes several life mortality tables (pyliferisk.mortalitytables), mainly extracted from academic textbooks. Nevertheless, additional libraries as Numpy or Pandas may be required for increasing functionality, such as cash flow operations, random number generation, interpolation, etc.

You can find also examples for different life contracts in the examples section.

# Why Python?

Because computing plays an important role in the actuarial profession, but actuaries are not programmers. Python is friendly and easy to learn.

Nowadays, programming is becoming an indispensable skill for actuaries. Python is a clear, readable syntax, powerful and fast language. Easy to learn, especially when you are not used to coding. This language lets you write quickly the code you need, without cumbersome rules or variable predefined tasks. It is clear, forget ending with commas and using curly brackets in functions.

For European actuaries, Solvency II opens a big opportunity. The new requirements transform into agility, transversality, and auditability. The internal model is not only software, but it should also be an internal process used extensively where all parts must walk hand in hand.

#### Python 3 and 2.7

Pyliferisk is compatible with both version: 3.x and 2.7

# Potential uses

This library may be used in tariff processes, in the design phase of new products such as profit testing or estimation of future benefits. Other uses include:

- Auditing purposes tool
- Assumption calibrations, back-testing, etc..
- Replicate the main calculations of the internal model for implementation in pricing, product approval, reserving, etc..
- Perform small reports (output format may be xml, xls, etc...)

If you find something that Python cannot do, or if you need the performance advantage of low-level code, you can write or reuse extension modules in C or C++.

## Installation

Once Python is running, just install this library with pip install

```
> pip install pyliferisk
```

Then, to import this library in projects is automatic as usually:

Option 1:

```
from pyliferisk import *
from pyliferisk.mortalitytables import *

tariff = MortalityTable(nt=GKM95)
```

Option 2:

```
import pyliferisk as life
import pyliferisk.mortalitytables as mort

tariff = life.MortalityTable(nt=mort.GKM95)
```

Option 3, if only like to use specific functions:

```
from pyliferisk import MortalityTable
from pyliferisk.mortalitytables import GKM95

tariff = MortalityTable(nt=GKM95)
```

# Update library

Run this command from terminal:

```
> pip install pyliferisk --upgrade
```

## License

This program is free software: you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation, either version 3 of the License, or any later version.

# 2 Pyliferisk: List of formulas

The names of the formulas follow the International Actuarial Notation and are easily guessable (qx, lx...) with a few exceptions regarding special characters.

## 2.1 Biometric functions: Class MortalityTable

The Instance Variables for the MortalityTable() class are:

• nt = The actuarial table used to perform life contingencies calculations. Syntax: nt = GKM95 (Note: GKM95 must be created previously or be included in mortalitytables.py) Example:

```
tariff = MortalityTable(nt=GKM95)
```

• perc = Optional variable to indicate the percentage of mortality to be applied. Syntax: perc=85. Variable perc can be omitted, in this case it will be 100 by default. Example:

```
experience = MortalityTable(nt=GKM95, perc=85)
```

Once define the variables for your mortality table, all available biometric functions are the following:

#### $2.1.1 \quad method .qx[x]$

```
      Description
      Returns the probability that a life aged x dies before 1 year

      With the convention: the true probability is qx/1000

      Actuarial notation
      q_x

      Usage
      mt.qx[x]

      Args
      x: the age as integer number.

      Example
      tariff = MortalityTable(nt=SPAININE2004)

      tariff.qx[50]
```

#### $2.1.2 \quad method \ .lx[x]$

```
        Description
        Returns the number of survivors at beginning of age x

        Actuarial notation
        l_x

        Usage
        mt.lx[x]

        Args
        x: the age as integer number.

        Example
        tariff.lx[50]
```

#### $2.1.3 \quad method$ .w

```
 \begin{array}{c|cccc} \textbf{Description} & \text{ultimate age (lw} = 0) \\ \textbf{Actuarial notation} & w \\ & \textbf{Usage} & \texttt{mt.w} \\ & \textbf{Example} & \texttt{tariff.w} \\ \end{array}
```

#### $2.1.4 \quad method \text{ mt.dx}[x]$

#### $2.1.5 \quad method \cdot ex[x]$

# Example:

Print the omega (limiting age) of the both mortality tables and the qx at 50 years-old:

```
#!/usr/bin/python
    from pyliferisk import MortalityTable
    from pyliferisk.mortalitytables import SPAININE2004, GKM95
3
4
    tariff = MortalityTable(nt=SPAININE2004)
5
    experience = MortalityTable(nt=GKM95, perc=85)
6
7
    # Print the omega (limiting age) of the both tables:
8
    print(tariff.w)
9
    print(experience.w)
10
11
    # Print the qx at 50 years old:
12
    print(tariff.qx[50] / 1000)
    print(experience.qx[50] / 1000)
```

Return the following results:

```
101
121
0.003113
0.003662395
```

## 2.2 Actuarial Present Value: Class Actuarial

The Present Value of the benefit payment is a function of time of death given a survival model and an interest rate.

The Instance Variables for the Actuarial() class are:

- nt = The actuarial table used to perform life contingencies calculations. Syntax: nt=GKM95 (Note: GKM95 must be included in mortalitytables.py)
- i = interest rate. The effective rate of interest, namely, the total interest earned in a year. Syntax: i=0.02
- perc = Optional variable to indicate the percentage of mortality to be applied. Syntax: perc=85. Variable perc can be omitted, in this case, it will be 100 by default.

```
tariff = Actuarial(nt=GKM95, i=0.05)
```

#### 2.2.1 *formula* Ax()

**Description** | Returns the Expected Present Value (EPV) of a whole life

insurance (i.e. net single premium). It is also commonly referred to as

the Actuarial Value or Actuarial Present Value.

Actuarial notation  $A_x$ 

Usage | Ax(mt, x)

**Args** mt: Mortality table.

x: the age as integer number.

Example | mt = Actuarial(nt=SPAININE2004, i=0.02)

Ax(mt, 50)

## 2.2.2 *formula* Axn()

**Description** | Returns the EPV (net single premium) of a term insurance.

Actuarial notation  $A_{x \cdot \overline{y}}^{1}$ 

Usage Axn(mt, x, n)

Args mt: Mortality table.

x: the age as integer number.

n: period in years.

Example | mt = Actuarial(nt=SPAININE2004, i=0.02)

Axn(mt, 50, 10)

#### 2.2.3 formula qAx()

**Description** | This function evaluates the APV of a geometrically increasing annual annuity-due.

Actuarial notation  $| _{q}A_{x}$ 

Usage | Axn(mt, x, q)

Args | mt: Mortality table.

x: the age as integer number.

q: increase rate.

Example | mt = Actuarial(nt=SPAININE2004, i=0.02)

Axn(mt, 50, 0.03)

#### 2.2.4 formula qAxn()

**Description** | This function evaluates the APV of a geometrically increasing Term insurance.

Actuarial notation  $| _{q}A_{x:\overline{n}|}$ 

Usage | qAxn(nt, x, n, q)

**Args** mt: Mortality table.

x: the age as integer number.

n: period in years.

q: increase rate.

Example | mt = Actuarial(nt=SPAININE2004, i=0.02)

Axn(mt, 50, 10, 0.03)

#### 2.2.5 formula AExn()

**Description** | Returns the EPV of an endowment insurance.

An endowment insurance provides a combination of a term insurance

and a pure endowment

Actuarial notation  $A_{x:\overline{n}}$ 

Usage | AExn(mt, x, n)

**Args** mt: Mortality table.

x: the age as integer number.

n: period in years.

Example | mt = Actuarial(nt=SPAININE2004, i=0.02)

AExn(mt, 50, 10)

#### Syntax:

Notation	Description	Syntax
$A_x$	whole-life death insurance	Ax(nt, x)
$A^1_{x:\overline{n}}$	Term insurance	Axn(nt, x, n)
$A_{x:\overline{n}}$	Endowment insurance	AExn(nt, x, n)
$_{q}A_{x}$	Increasing whole-life	qAx(nt, x, n)
$qA_{x:\overline{n}}$	Increasing Term insurance	qAxn(nt, x, n, q)

# **Examples:**

1) A whole-life single premium:

#### 589.0804423991423

2) A term insurance single premium:

```
#!/usr/bin/python
   from pyliferisk import Actuarial, Axn
2
   from pyliferisk.mortalitytables import GKM95
3
4
   mt = Actuarial(nt=GKM95, i=0.03)
5
   x = 40
            #age
6
   n = 20
                 #horizon
   C = 10000
                 #capital
  print(Axn(mt, x, n) * C)
10
```

646.1486398262324

3) Example 2 with cashflow approach:

```
#!/usr/bin/python
    from pyliferisk import MortalityTable
2
    from pyliferisk.mortalitytables import GKM95
3
    import numpy as np
4
5
   mt = MortalityTable(nt=GKM95)
   x = 40
7
                   #age
   n = 20
                    #horizon
   C = 10000
                   #capital
9
                   #interest rate
   i = 0.03
10
11
    payments = []
12
   for t in range(0, n):
13
       payments.append((mt.lx[x+t] - mt.lx[x+t+1]) / mt.lx[x] * C)
14
15
    discount_factor = []
16
   for y in range(0, n):
       discount_factor.append(1 / (1 + i) ** (y + 0.5))
18
19
    print(np.dot(discount_factor, payments).round(2))
20
```

#### 646.1486398262326

To print the results year by year:

```
print('{0:5} {1:10} {2:10}'.format(' t','factor','payment'))

for t in range(0,n):
    print('{0:2} {1:10} {2:10}'.format(t, np.around(discount_factor[t],5), np.around(payments[t],4)))
```

```

# 2.3 Annuity formula

A life annuity refers to a series of payments to an individual as long as the individual is alive on the payment date. It may be temporary or payable for whole-life. The payment intervals may commence immediately or deferred. The payment may be due at the beginnings of the intervals (annuity due) or at the end (annuity immediate).

#### 2.3.1 function annuity()

```
Description
                Returns the actuarial present value of annuity payments
      Usage
                annuity(mt, x, n, 0/1, m=1,['a'/'g',q], -d)
        Args
                              the mortality
           1.
                    mt
           2.
                              The age of the insured
                     \mathbf{x}
                              The horizon (term of insurance) in years or payment duration or
           3.
                  or 'w'
                              w as whole-life. Also 99 is defined as whole-life.
                     0
                              annuity-immediate
           4.
                   or 1
                              annuity-due
optional args:
                    m:
                              Number of fractional payments per period. If missing, m is set as 1
                  ['a', q]
                              Arithmetically increasing
                or \ ['g', q]
                              Geometrically increasing
                    -d
                              The deferring period in years (as negative integer)
```

## **Examples:**

1) The present value of a 5-year (financial) annuity with nominal annual interest rate 12% and monthly payments of \$100 is:

```
#!/usr/bin/python
from pyliferisk import *
import numpy as np

mt = Actuarial(nt=FIN, i=0.12/12) #FIN = Financial table

n = 5 * 12
C = 100

print(annuity(mt, 0, n, 1) * C) #replace age 'x' by 0
```

Returns:

#### 4495.503840622397

The equivalent formula in Excel is: PV(12%/12,12\*20,500,,0)

2) Premium calculation: A Life Temporal insurance for a male, 30 years-old and a horizon of 10 years, fixed annual premium (GKM95, interest 6%):

Actuarial equivalence:  $\pi^1_{30:\overline{10}|} = 1000 \cdot \frac{A^1_{30:\overline{10}|}}{\ddot{a}_{30:\overline{10}|}}$ 

```
#!/usr/bin/python
   from pyliferisk import *
2
   from pyliferisk.mortalitytables import GKM95
3
4
   nt = Actuarial(nt=GKM95, i=0.06)
5
   x = 30
6
   n = 10
7
   C = 1000
   print(C * (Axn(nt, x, n) / annuity(nt, x, n, 0)))
```

#### 1.398266715155939

3) Reserving a life risk insurance with regular premium. Applying the equivalence principle, where:

```
_{0}V_{x} = A_{x} - \pi \cdot \ddot{a}_{x} = 0 and: \pi = \frac{A_{x:\overline{n}|}^{1}}{\ddot{a}_{x:\overline{n}|}}. At time t: _{t}V_{x} = A_{40+t:\overline{10-t}|}^{1} - \pi \cdot \ddot{a}_{40+t:\overline{10-t}|}
```

```
#!/usr/bin/python
1
    from pyliferisk import *
2
   from pyliferisk.mortalitytables import GKM95
3
4
   nt = Actuarial(nt=GKM95, i=0.03)
5
   x = 40
6
   n = 20
7
    Cm = 100000
    Premium = Cm * Axn(nt, x, n) / annuity(nt, x, n, 0) #fixed premium
9
10
    def Reserve(t):
11
      return round(Cm * Axn(nt, x+t, n-t)
12
                                     - Premium * annuity(nt, x+t, n-t, 0),2)
13
14
  for t in range(0, n+1):
15
   print(t, Reserve(t))
16
```

```
1 257.11
2 509.4
3 755.01

19 603.61
```

# Actuarial notation vs. Syntax formula

Notation	Description	Syntax		
$\ddot{a}_{x:\overline{n}}$	n-year temporary life annuity-due	annuity(nt,x,n,0)		
$a_{x:\overline{n}}$	n-year temporary life annuity	annuity(nt,x,n,1)		
$\ddot{a}_{x:\overline{n}}^{(m)}$	n-year annuity-due m-monthly payments	annuity(nt,x,n,0,m)		
$\ddot{a}_x$	whole life annuity-due	annuity(nt,x,'w',0)		
$a_x$	whole life annuity	annuity(nt,x,'w',1)		
$\ddot{a}_x^{(m)}$	whole life annuity-due m-monthly	annuity(nt,x,'w',0,m)		
$a_x^{(m)}$	whole life annuity m-monthly	annuity(nt,x,'w',1,m)		
$n \ddot{a}_x$	d-year deferred whole life annuity- due	annuity(nt,x,n,0,-d)		
$n a_x$	d-year deferred whole life annuity	annuity(nt,x,n,1,-d)		
$n \mid \ddot{a}_{x:\overline{n} \mid}^{(m)}$	d-year deferred n-year temporal annuity-due m-monthly payments	annuity(nt,x,n,0,m,-d)		
$n \mid \ddot{a}_x$	d-year deferred whole life annuity- due	annuity(nt,x,'w',0,-d)		
$n a_x$	d-year deferred whole life annuity	annuity(nt,x,'w',1,-d)		
Increasing annuities (a sample of them)				
$q\ddot{a}_x$	geometrically increasing whole-life annuity-due	annuity(nt,x,'w',0,['g',c])		
$ a_x $	d-year deferred geometrically increasing whole-life annuity-due	annuity(nt,x,'w',0,['g',c],-d)		
$q \ddot{a}_{x:\overline{n}}^{(m)}$	d-year deferred geometrically in- creasing n-year temporal annuity- due m-monthly payments	annuity(nt,x,n,0,m,['g',c],-d)		

# 2.4 Pure endowment: Deferred capital

#### 2.4.1 formula nEx()

#### Syntax:

Notation	Description	Syntax
$A_{x:\overline{n}}$	Pure endowment (Deferred capital)	nEx(nt, x, n)
$_{n}E_{x}$	EPV of a pure endowment (deferred capital)	nEx(nt, x, n)

# Example:

A deferred capital premium calculation:

```
#!/usr/bin/python
    from pyliferisk import *
2
    from pyliferisk.mortalitytables import GKM80
3
4
    C = 1000
5
    x = 60
6
    n = 25
7
    exp = 0.2 / 100
                            # expenses over capital
    com = 0.10
                             # commision over premium
9
10
11
    mt = Actuarial(nt=GKM80, i=0.025)
12
13
    def Premium(mt, x, n):
     return (nEx(mt, x, n) + Axn(mt, x, n)) / annuity(mt, x, n, 0) * C
14
15
    print((Premium(mt, x, n) + C * exp) / (1 - com))
16
```

Returns:

58.8146911381352

#### 2.5 Commutation factors

Nowadays, the standard techniques for actuarial calculations use cashflow projections. In fact, the use of interest rates curves is required for the calculation of the technical provisions for insurance obligations (such as risk-free interest rate term structures in Solvency II framework) where commutation factors are not adequate.

Despite commutation factors may seem quite prehistoric, it may be useful for academic purposes or replicating older products exactly "to the letter". For this reason, the pyliferisk library includes a list of commutations factors (Dx, Nx, Cx, Mx) in order to facilitate the migration from older actuarial software (such as Cobol or Cactus) to Python, or for simple calculations (where your model shouldn't be subject to future changes). If your goal is to reduce the timing, there are a lot of other aspects where you can save time.

```
#!/usr/bin/python
from pyliferisk import *
from pyliferisk.mortalitytables import GKM95

tariff = Actuarial(nt=GKM95, i=0.02)

print(tariff.Dx[50])
print(tariff.Nx[50])
print(tariff.Cx[50])
print(tariff.Cx[50])
print(tariff.Mx[50])
```

Returns:

```
35633.87396668312
844266.356048293
109.8353338458543
19269.483448767027
```

# 2.6 Other functions

Other functions can be derived from the lx figures. Anyway, the library include the following additional formulas:

- px(mt, x): Returns the probability of surviving within 1 year  $(p_x)$ .
- tpx(mt, x, t): Returns the probability that x will survive within t years  $(p_x)$ .
- tqx(mt, x, t): Returns the probability to die within n years at age x  $(t_{q_x})$ .
- tqxn(mt, x, n, t): Probability to die in n years being alive at age x  $(n|q_x)$ .
- mx(mt, x): Returns the central mortality rate  $(m_x)$ .

# 2.7 Help (Documentation strings)

According Python PEP257 convention, formulas includes a documentation string (also known as docstrings):

```
#!/usr/bin/python
from pyliferisk import *

print(qx.__doc__)
```

Returns:

```
qx: Returns the probability that a life aged x dies before 1 year
With the convention: the true probability is qx/1000
Args:
mt: the mortality table
x: the age as integer number.
```

# 3 Mortality tables

The package includes a sample of life mortality tables (mortalitytables.py), mainly extracted from academic textbooks or contributions. It's possible to add tables as a list or to import tables of an external source, i.e. txt or csv files (see Example 6).

Tables must be imported for use, either all (import \*) or only which you will use, example:

```
from pyliferisk.mortalitytables import GKM95, UK43
```

Notes:

- The probability is qx \* 1000.
- The first item indicates the age when the table starts. For example, UK43 table is 0 for the first 30 ages.

There is a financial table (called FIN) for financial annuities which doesn't include mortality.

In the SOA repository (http://mort.soa.org) is available a variety (over 2,500) of rate tables of interest to actuaries: SOA experience mortality and lapse tables, regulatory valuation tables, population tables and various international tables).

## 3.1 Adding tables

#### 3.1.1 Probability of dying tables (qx)

Probability of dying between age x and x+1 tables (qx tables of mortality tables) are added in list format where first item indicates the age when table starts. ie:

```
SCOT_DLT_00_02_M = [0, 0.006205, 0.000328, 0.00026 ....]
```

#### 3.1.2 Number of surviving tables (lx)

In case you need to use an surviving table (with numbers of surviving to age x) it's possible using the following instruction:

```
from pyliferisk import MortalityTable

lx_sample = [100000,99500,99250,99200,99000,98900]

mt = MortalityTable(lx=lx_sample)

print(mt.qx[0]/1000)
print(mt.qx[1]/1000)
print(mt.qx[2]/1000)
```

```
0.005
0.002512
0.000503
```

See Example 6 where an external file is read.

# 3.2 Class .view()

Instruction .view() provides a view of the main variables (qx, lx, dx, ex, Dx, Nx, Cx, Mx, nEx) of any mortality table. The default view is lx for 10-years. Usage example:

```
mt = MortalityTable(nt=INM05)
nt.view()
```

```
[x=0] lx=100000.0

[x=1] lx=99564.1

[x=2] lx=99530.7460265

[x=3] lx=99506.659586

[x=4] lx=99488.4498673

[x=5] lx=99473.4271113

[x=6] lx=99460.6945127

[x=7] lx=99448.1624651

[x=8] lx=99435.5325485

[x=9] lx=99421.9098806

[x=10] lx=99409.3827199

Total number of rows for lx = 107
```

Other view (qx from 60 to 65 years-old):

```
mt = MortalityTable(nt=INM05)
nt.view(60, 65, var = 'qx')
```

```
[x=60] qx=9.958

[x=61] qx=10.736

[x=62] qx=11.199

[x=63] qx=12.455

[x=64] qx=13.861

[x=65] qx=15.224

Total number of rows for qx = 106
```

# 4 Examples

This section includes a list of examples using pyliferisk.

# 4.1 Example 1. Cashflow calculation: Annuity-immediate Geometrically increasing

Prospective Reserves look forward, as the expected present value of future outgo less the expected present value of the future income. Using NumPy library for discount them.

Life annuity immediate geometrically increasing for a male 67 years-old, as single premium (PASEM2010, interest 5%):

```
#!/usr/bin/python
    import pyliferisk as life
2
    from pyliferisk.mortalitytables import SPAIN_PASEM2010M
3
    import numpy as np
4
5
    mt = life.MortalityTable(nt=SPAIN_PASEM2010M)
6
    age = 67
    initial_payment = 8000
9
    incr = 0.03
10
                                              # increment
    i = 0.05
                                              # interest rate
11
12
    discount_factor = []
13
    for y in range(0, mt.w-age):
14
            discount_factor.append(1 / (1 + i) ** (y + 1))
15
16
    payments = [initial_payment]
17
    for x in range(0, mt.w-age-1):
18
            payments.append(payments[x] * (1 + incr) * (1 - mt.qx[age+x] /
                1000))
20
    print('Premium:', np.dot(payments, discount_factor).round(2))
21
```

Premium: 96718.36

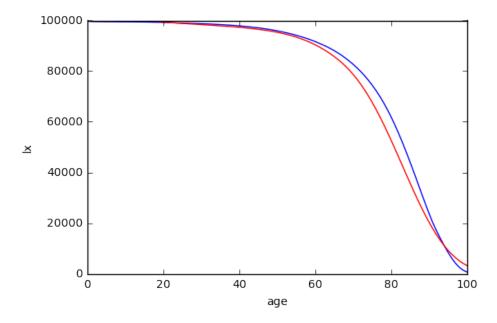

There are different ways of discounting (see previous line 15). In case of:

- not discount first year: the exponent should be only y.
- discount first year: the exponent should be y+1.
- discount half year: the exponent should be y+0.5.

# 4.2 Example 2. Drawing graph with matplotlib

Plotting a surviving graph with pyplot library:

```
#!/usr/bin/python
   import matplotlib.pyplot as plt
2
   import pyliferisk as life
3
   from pyliferisk.mortalitytables import SPAININE2004, GKM95
   tariff = life.MortalityTable(nt=SPAININE2004)
   experience = life.MortalityTable(nt=GKM95, perc=75)
   x = range(0, tariff.w)
   y = tariff.lx[:tariff.w]
   z = experience.lx[:tariff.w]
10
   plt.plot(x,y, color = 'blue')
11
   plt.plot(x,z, color = 'red')
   plt.ylabel('lx')
13
   plt.xlabel('age')
```

## 4.3 Example 3. Obtain data from plain text file

Term Life with maturity capital benefit and similar death capital.

```
#!/usr/bin/python
    from pyliferisk import *
2
    from pyliferisk.mortalitytables import SPAININE2004, GKM95
3
    import csv
4
    mt = Actuarial(nt=GKM80, i=0.04)
6
7
    def single_risk_premium(x, n):
       return nEx(mt, x, n) + Axn(mt, x, n)
9
10
    def annual_risk_premium(x, n):
11
       return (single_risk_premium(x, n) / annuity(mt, x, n, 0))
12
13
    SingleRiskPrem = []
14
    AnnualRiskPrem = []
15
16
    columns = '{0:8} {1:2} {2:9} {3:8} {4:10} {5:10}'
17
    print(columns.format('Contract', 'Age', 'Duration', 'Capital', 'Single Pr
       ', 'Annual Pr'))
    print('--' * 26)
19
20
    with open('colective.csv', 'r') as file:
21
        colective = csv.DictReader(file, delimiter=';')
22
        for row in colective:
23
            age = int(row['age'])
24
            dur = int(row['duration'])
25
            capital = int(row['capital'])
            single_premium = round(capital * single_risk_premium(age, dur),
27
                2)
            annual_premium = round(capital * annual_risk_premium(age, dur),
28
                2)
            AnnualRiskPrem.append(annual_premium)
29
            print(columns.format(row['N_pol'], age, dur, capital,
30
                single_premium, annual_premium))
31

Even is possible to read directly from any site with the urllib2, Scrapy or BeautifulSoup4 (a screen-scraping libraries for parsing HTML and XML).

# 4.5 Example 5. Cashflow Calculation Reserving

Reserving for a Whole Life contract using a lineal interest rate and the risk-free rate obtained in the previous example.

Once again, the following two examples should be enough clear:

#### Using lineal interest rate

```
#!/usr/bin/python
    from pyliferisk import *
2
    from pyliferisk.mortalitytables import INM05
3
    import numpy as np
4
5
    tariff = Actuarial(nt=INMO5, i=0.05)
6
    reserve = MortalityTable(nt=INM05)
7
    age = 32
                                      # age
8
    Cd = 3000
                                      # capital death
9
    Premium = Cd * Ax(tariff, 25) / annuity(tariff, 25, 'w', 0) #fixed at age
10
        25
11
    qx\_vector = []
12
    px_vector=[]
13
    for i in range(age, reserve.w + 1):
14
            qx = ((reserve.lx[i] - reserve.lx[i+1]) / reserve.lx[age])
15
            qx_vector.append(qx)
16
            qx_sum = sum(qx_vector)
17
            px_vector.append(1 - qx_sum)
18
19
    def Reserve(i):
20
21
            discount_factor = []
22
            for y in range(0, reserve.w-age + 1):
                     discount_factor.append(1 / (1 + i) ** (y + 1))
23
24
            APV_Premium = np.dot(Premium, px_vector)
25
            APV_Claims = np.dot(Cd, qx_vector)
26
            # Reserve = APV(Premium) - APV(Claim)
27
            return np.dot(discount_factor, np.subtract(APV_Claims,
28
                APV_Premium)).round(2)
29
    print(Reserve(0.0191))
30
    print (Reserve (0.0139))
```

```
820.8
1088.37
```

#### Including risk free rate curve

```
#!/usr/bin/python
    from pyliferisk import *
2
    from pyliferisk.mortalitytables import INM05
3
    import numpy as np
4
    import pandas as pd
5
    rfr = pd.read_excel('EIOPA_RFR_20161231_Term_Structures.xlsx', sheet_name
       ='RFR_spot_no_VA', skiprows=9, usecols='C:C', names=['Euro'])
    tariff = Actuarial(nt=INM05, i=0.05)
9
    reserve = MortalityTable(nt=INM05)
10
                             # age
    x = 32
11
    Cd = 3000
                             # capital death
12
    Premium = Cd * Ax(tariff, 25) / annuity(tariff, 25, 'w', 0)
13
14
    qx\_vector = []
15
    px_vector = []
16
    for i in range(x,reserve.w + 1):
            qx = ((reserve.lx[i]-reserve.lx[i+1]) / reserve.lx[x])
            qx_vector.append(qx)
19
            qx_sum = sum(qx_vector)
20
            px_vector.append(1 - qx_sum)
21
22
    def Reserve(i):
23
            discount_factor = []
24
            for y in range(0, reserve.w - x + 1):
25
                    if isinstance(i,float):
26
                             discount_factor.append(1 / (1 + i) ** (y + 1))
27
                     elif i == 'rfr':
                             discount_factor.append(1 / (1 + rfr['Euro'][y])
29
                                 ** (y + 1))
30
            APV_Premium = np.dot(Premium, px_vector)
31
            APV_Claims = np.dot(Cd, qx_vector)
32
            return np.dot(discount_factor, np.subtract(APV_Claims,
33
                APV_Premium)).round(2)
34
    print(Reserve(0.0191))
    print(Reserve(0.0139))
    print(Reserve('rfr'))
```

```
820.8
1088.37
544.31
```

# 4.6 Example 6. Import a mortality table (lx) using pandas

Normally, we will have the tables in an external file in xls or csv format. In this case, we can use the instruction read\_csv or read\_xls of pandas.

Example 3.3.1 from Actuarial Mathematics, by Newton L. Bowers (et al.), Society of Actuaries, 1997 (pg. 64)

```
#!/usr/bin/python
    import pandas as pd
2
    from pyliferisk import MortalityTable
3
4
    USLife1979 = pd.read_csv('uslife79.csv')
5
    USLife791x = USLife1979['lx'].tolist()
6
7
    mt = MortalityTable(lx=USLife79lx)
8
    print('Live to 100:', mt.lx[100]/mt.lx[20])
10
    print('Die before 70:', 1 - mt.lx[70]/mt.lx[20])
11
    print('Die in the tenth decade of life:', (mt.lx[90]-mt.lx[100])/mt.lx
       [20])
13
14
    print('Probability of death between 50 and 51:',
15
           (mt.lx[50] - mt.lx[51]) / mt.lx[50])
16
    print('Likewise with qx:', mt.qx[50] / 1000)
17
    print('Ultimate age:', mt.w)
18
```

```
Live to 100: 0.0118
Die before 70: 0.30178
Die in the tenth decade of life: 0.1330
```

Additional exercises not included in book:

```
Probability of death between 50 and 51: 0.0058999
Likewise with qx: 0.0058999
Ultimate age: 109
```

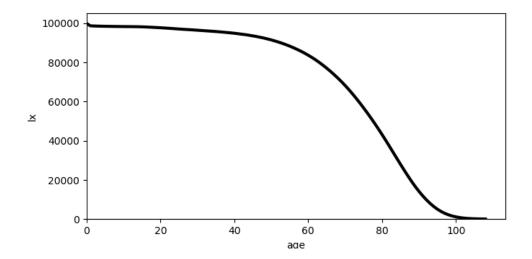

Figure 3.3.3 from Actuarial Mathematics, by Newton L. Bowers (et al.), 1997 (pg. 65)

```
#!/usr/bin/python
import pandas as pd
from pyliferisk import MortalityTable
import matplotlib.pyplot as plt

USLife1979 = pd.read_csv('uslife79.csv')
USLife79lx = USLife1979['lx'].tolist()

mt = MortalityTable(lx=USLife79lx)

x = range(0, mt.w)
y = mt.lx[:mt.w]

# 5 Books

The author has checked the library with examples from the following textbooks:

- Actuarial Mathematics for Life Contingent Risks (David C. M. Dickson, Mary R. Hardy and Howard R. Waters) Cambridge University Press, 2009.
- $\bullet\,$  Actuarial Mathematics (2nd Edition), Newton L. Bowers (et al.), Society of Actuaries, 1997.
- Matemática de los Seguros de Vida, (Gil Fana J.A., Heras Matínez A. and Vilar Zanón J.L.) Fundación Mapfre Estudios, 1999.

It will be documented in the examples folder. Contributions are greatly appreciated.

# 6 Acknowledgements

My special thanks for all the contributions, suggestions and discussion to Florian Pons (France), Mason Borda (US), Sunil Subbakrishna (US), Arief Anbiya (Indonesia) and Marios Cheristanidis.
